

Amendments to the Claims:

This listing of claims will replace all prior versions, and listings, of claims in the application.

Listing of Claims:

1. (Currently Amended) A method comprising:
 - in response, at least in part, to a request for a service from a system, determining a quality of service to assign to an application to be executed by the system to provide the service, the quality of service based, at least in part, on one or more service characteristics of the application;
 - mapping said one or more service characteristics to a class of service database, wherein a class of service corresponds to one or more service characteristics to which the application service characteristics can be mapped to determine the application's class of service;
 - allocating one or more resources to the application, the one or more resources being based, at least in part, on the quality of service and a media access control service data unit (MSDU) size;
 - determining a size of packets to be used for transmitting data associated with the service based on said quality of service; and
 - servicing the application in a bearer plane.
2. (Original) The method of claim 1, wherein the system comprises a modified intelligent media center (MIMC), and said determining a quality of service to assign to an application to be executed by the system to provide the service comprises determining a quality of service to assign to a multimedia application to be executed by the MIMC to provide the service.
3. (Original) The method of claim 2, wherein said determining the quality of service to assign to the multimedia application comprises assigning one or more QoS (quality of service) parameters to the application, the QoS parameters being based

on a class of service associated with the one or more service characteristics of the multimedia application.

4. (Original) The method of claim 3, wherein the multimedia application is a wireless application, and the one or more QoS parameters comprise at least one of:
AIFS (arbitration inter-frame space);
 CW_{min} (minimum contention window);
 CW_{max} (maximum contention window); and
PF (persistence factor).
5. (Original) The method of claim 3, wherein said determining the quality of service to assign to the multimedia application additionally comprises determining a size of packets to be used for transmitting data associated with the multimedia application from the system to a client.
6. (Original) The method of claim 5, wherein said determining the size of packets comprises determining a size of an MSDU (MAC – media access layer – service data unit) based, at least in part, on at least one of the one or more service characteristics.
7. (Original) The method of claim 6, wherein said determining the size of the data packets additionally comprises determining the size of the MSDU based, at least in part, on a priority associated with the class of service.
8. (Original) The method of claim 1, wherein said allocating the one or more resources to the application based, at least in part, on the quality of service comprises assigning at least one of:
a processing throughput;
a queue length; and

memory buffer size.

9. (Original) The method of claim 1, additionally comprising:
 queuing the application for servicing; and
 scheduling the application for servicing.
10. (Currently Amended) An apparatus comprising:
 circuitry operating in a bearer plane of a communications environment, said
 circuitry capable of:
 in response, at least in part, to a request for a service from a system,
 determining a quality of service to assign to an application to be executed by the
 system to provide the service, the quality of service based, at least in part, on one
 or more service characteristics of the application;
 mapping said one or more service characteristics to a class of service
 database, wherein a class of service corresponds to one or more service
 characteristics to which the application service characteristics can be mapped to
 determine the application's class of service;
 allocating one or more resources to the application, the one or more
 resources based, at least in part, on the quality of service and a media access
 control service data unit (MSDU) size; and
 determining a size of packets to be used for transmitting data associated
 with the service based on said quality of service.
11. (Original) The apparatus of claim 10, wherein the system comprises a modified
 intelligent media center (MIMC), and the circuitry that is capable of determining
 a quality of service to assign to an application to be executed by the system to
 provide the service is capable of determining a quality of service to assign to a
 multimedia application to be executed by the MIMC to provide the service.
12. (Original) The apparatus of claim 11, wherein said circuitry capable of

determining the quality of service to assign to the multimedia application is also capable of assigning one or more QoS (quality of service) parameters to the multimedia application.

13. (Original) The apparatus of claim 12, wherein the multimedia application is a wireless application, and the one or more QoS parameters comprise at least one of:

AIFS (arbitration inter-frame space);
 CW_{\min} (minimum contention window);
 CW_{\max} (maximum contention window); and
PF (persistence factor).

14. (Original) The apparatus of claim 12, wherein said circuitry capable of determining the quality of service to assign to the multimedia application is also capable of determining a size of packets to be used for transmitting data associated with the multimedia application from the system to a client.

15. (Original) The apparatus of claim 10, wherein said circuitry capable of allocating the one or more resources to the application based, at least in part, on the quality of service is also capable of assigning at least one of:

a processing throughput;
a queue length; and
memory buffer size.

16. (Original) The apparatus of claim 10, additionally said circuitry additionally capable of:

queuing the application for servicing; and
scheduling the application for servicing.

17. (Currently Amended) A system comprising:

one or more applications to be executed to provide one or more services to one or more clients;

one or more resources to support the execution of the one or more applications;

a wireless network interface card to receive from the one or more clients, one or more requests for a service; and

circuitry communicatively coupled to the wireless network interface card, and capable of:

in response, at least in part, to a request for a service, determining a quality of service to assign to one of the applications to provide one of the one or more services, the quality of service based, at least in part, on one or more service characteristics of the application;

mapping said one or more service characteristics to a class of service database, wherein a class of service corresponds to one or more service characteristics to which the application service characteristics can be mapped to determine the application's class of service;

allocating at least one of the one or more resources to the application, the at least one of the one or more resources based, at least in part, on the quality of service and a media access control service data unit (MSDU) size; and

determining a size of packets to be used for transmitting data associated with the service based on said quality of service;

wherein said circuitry is capable of operating in a bearer plane of a communications environment.

18. (Original) The system of claim 17, wherein the system comprises a modified intelligent media center (MIMC), and the circuitry that is capable of determining a quality of service to assign to an application to be executed by the system to provide the service is capable of determining a quality of service to assign to a multimedia application to be executed by the MIMC to provide the service.

19. (Original) The system of claim 18, wherein said circuitry capable of determining the quality of service to assign to the multimedia application is also capable of assigning one or more QoS (quality of service) parameters to the multimedia application.
20. (Original) The system of claim 19, wherein said circuitry capable of determining the quality of service to assign to the multimedia application is also capable of determining a size of packets to be used for transmitting data associated with the multimedia application from the system to the client.
21. (Original) The system of claim 17, wherein said circuitry capable of allocating the one or more resources to the multimedia application based, at least in part, on the quality of service is also capable of assigning at least one of:
a processing throughput;
a queue length; and
memory buffer size.
22. (Original) The system of claim 17, additionally said circuitry additionally capable of:
queuing the application for servicing; and
scheduling the application for servicing.
23. (Canceled)
24. (Currently Amended) A machine-readable medium having stored thereon instructions, the instructions when executed by a machine, result in the following:
in response, at least in part, to a request for a service from a system, determining a quality of service to assign to an application to be executed by the system to provide the service, the quality of service based, at least in part, on one or more service characteristics of the application;

mapping said one or more service characteristics to a class of service database, wherein a class of service corresponds to one or more service characteristics to which the application service characteristics can be mapped to determine the application's class of service;

allocating one or more resources to the application, the one or more resources based, at least in part, on the quality of service and a media access control service data unit (MSDU) size;

determining a size of packets to be used for transmitting data associated with the service based on said quality of service; and

servicing the application in an abearer plane.

25. (Original) The machine-readable medium of claim 24, wherein the system comprises a modified intelligent media center (MIMC), and said instructions that result in determining a quality of service to assign to the application result in determining a quality of service to assign to a multimedia application to be executed by the MIMC to provide the service.

26. (Original) The machine-readable medium of claim 25, wherein said instructions that result in determining the quality of service to assign to the multimedia application result in assigning one or more QoS (quality of service) parameters to the multimedia application.

27. (Original) The machine-readable medium of claim 26, wherein the multimedia application is a wireless application, and the one or more QoS parameters comprise at least one of:

AIFS (arbitration inter-frame space);
 CW_{min} (minimum contention window);
 CW_{max} (maximum contention window); and
PF (persistence factor).

28. (Original) The machine-readable medium of claim 26, wherein said instructions, when executed by a machine, that result in determining the quality of service to assign to the multimedia application additionally result in determining a size of packets to be used for transmitting data associated with the multimedia application from the system to a client.
29. (Original) The machine-readable medium of claim 24, wherein said instructions, when executed by a machine, result in allocating the one or more resources to the application based, at least in part, on the quality of service additionally result in assigning at least one of:
- a processing throughput;
 - a queue length; and
 - memory buffer size.
30. (Original) The machine-readable medium of claim 24, said instructions, when executed by a machine, additionally result in:
- queuing the application for servicing; and
- scheduling the application for servicing.
